1 Introduction

This document describes version 4.11 of the Aculab Prosody Group 3 fax software application programmer interface (API). The document does not cover the following:

- The Aculab Generic Call Control API, Appendix A:[4], which describes management of telephony resources.
- The Aculab Switch Driver API, Appendix A: [3], which enables switching of streams between resources and CT buses.
- TiNG API Guide, Appendix A: [1], which describes the Prosody TiNG Generic API and a host of other TiNG related topics.

For the Aculab Image Processing API guide please see Appendix A: [2]. This library contains various image manipulation tools.
2 Overviews

2.1 Firmware

A number of Prosody TiNG firmware files need to be downloaded to each media processing resource that is to be used for fax transmission and/or reception.

The Prosody TiNG firmware files necessary for Prosody Fax are listed in Appendix C. For more comprehensive information on firmware, see Appendix A: [1]

2.1.1 FAX channel counts for Prosody cards

The total channel count supported by each media processing resource in the system is dependent on the hardware architecture of the host system, the bus bandwidth available, and the performance of the local mass storage system.

Please contact Aculab technical support for the latest developments on Prosody channel counts.
3 Notes on T.30 over IP

It is becoming quite common for TDM calls (voice and data) to be routed over an IP link at some point. This has some implications for a data transfer such as fax. Below are some points to be aware of if you know that your T.30 fax is going to be sent via an IP link.

The IP link must be “fax aware” and default to use the G.711 codec only, no other codecs can be used.

Packet loss concealment must be off. IP uses packet loss concealment to mask missing packets in speech. But this is detrimental to a data transmission such as fax.

Comfort noise must be off. Comfort noise is used to mask digital silence which can be uncomfortable during a conversation, and can even lead to a participant thinking that he has been disconnected. But introducing noise in a fax transmission is a bad idea.

Echo cancellation must be off. Echo cancellers can modify the signal which must not happen during a data transmission.

Automatic gain control must be off. This can modify the signal, which is not allowed.

Adaptive jitter buffers must be off. Adaptive jitter buffers can alter the timing of packets and may introduce delays, fax relies on packets arriving promptly.

Ideally, there should be no packet loss, but minimal packet loss can be tolerated. If packet loss is going to occur it is recommended to minimise the size of image data chunks that are sent. Use ECM as that will send partial pages rather than whole pages and use higher compression techniques (MMR instead of MR). Also, if the packet loss is spaced quite far apart, it would be better to send the fax quickly, so use a faster modem (V.17 rather than V.27).
## 4 The API

</tr>
</tbody>
</table>
To transmit a fax, a Prosody Fax enabled application would do the following:

- Establish a call using the Aculab call control API, see Appendix A: [4].
- Allocate a full duplex Prosody channel, see Appendix A: [1].
- The established call is switched to the Prosody channel, using the Aculab switch API, see Appendix A: [3].
- Invoke `smfax_create_session` specifying the necessary parameters.
- Invoke `smfax_configure` to configure the session.
- Invoke `smfax_negotiate_caps`.
- If negotiation is successful call `smfax_load_page` to load a page from a Group 3 compliant TIFF file, previously opened with the Aculab ACTIFF API, see Appendix A: [2].
- Upon successful negotiation, invoke `smfax_tx_page_process` specifying the necessary parameters to transmit the loaded page. Remember to specify whether or not the page to be transmitted is the last page.
- Invoke `smfax_close_page` when the page transmission API returns.
- If there are more pages to send, load them like the previous page and then invoke the API to transmit the page.
- Invoke `smfax_close_session` to release resources used by the fax session.
- If it has no further use, free the allocated full duplex Prosody channel.

To receive a fax, a Prosody Fax enabled application would do the following:

- Establish a call using the Aculab call control API, see Appendix A: [4].
- Allocate a full duplex Prosody channel, see Appendix A: [1].
- The established call is switched to the Prosody channel, using the Aculab switch API, see Appendix A: [3].
- Invoke `smfax_create_session` specifying the necessary parameters.
- Invoke `smfax_configure` to configure the session.
- Invoke `smfax_negotiate_caps`.
- If negotiation is successful, invoke `smfax_rx_page_process` or `smfax_rx_page_process_with_retry_timeout`.
- After `smfax_rx_page_process` or `smfax_rx_page_process_with_retry_timeout` returns, invoke `smfax_store_page` to store the received page/image to a group 3 compliant TIFF file.
- Invoke `smfax_close_page` when the page reception API returns and the page is stored using the relevant API, or when convenient to the program architecture.
- If `smfax_rx_page_process` or `smfax_rx_page_process_with_retry_timeout` indicated, on return, that there are more pages, then `smfax_rx_page_process` or `smfax_rx_page_process_with_retry_timeout` must be called again and the page storage procedure must be repeated.
- Invoke `smfax_close_session` to release resources used by fax session.
- If it has no further use, free the allocated full duplex Prosody channel.
5 API headers and libraries

The prototype declarations of the API calls described in this document can be found in the ‘C’ language header file smfaxapi.h. This file includes the header files:

- actiff.h - interface to TIFF image accessing API, see Appendix A[2].
- smdrvr.h - interface to generic Prosody API calls, see Appendix A[1].

5.1 Library components

5.1.1 Microsoft Windows Linking

The library files (faxlib3_dll.lib and actiff.lib) for building a Prosody Fax enabled application can be found under the API/lib directory of the fax distribution. The dynamic link library files (faxlib3_dll.dll and actiff.dll) can be found in the bin subdirectory of the Aculab V6 installation directory.

<table>
<thead>
<tr>
<th>Component</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>faxlib3_dll</td>
<td>Aculab implementation of ITU-T T.30 recommendation.</td>
</tr>
<tr>
<td>actiff</td>
<td>API for accessing group 3 compliant TIFF files.</td>
</tr>
</tbody>
</table>

5.1.2 Linux linking

The library files for building a Prosody Fax enabled application are distributed as shared objects. The shared object libraries (libfaxlib.so and libactiff.so) can be found in the lib subdirectory of the Aculab V6 installation directory.

<table>
<thead>
<tr>
<th>Component</th>

6 API call descriptions

6.1 Fax session creation

6.1.1 SMFAX_TRANSPORT_MEDIUM_TDM

**Definition**

```c
typedef struct tSmfaxTransportMedium_TDM {
  tSMTDMrxId rx;  /* in */
  tSMTDMtxId tx;  /* in */
} SMFAX_TRANSPORT_MEDIUM_TDM;
```

**Description**

This structure allows the user to specify that TiNG TDM endpoints are to be used instead of the basic stream and time-slot TDM system. Please read the appropriate TiNG documentation (see Appendix A: [1]) on how to allocate and configure these types.

6.1.2 SMFAX_TRANSPORT_MEDIUM_VMP

**Definition**

```c
typedef struct tSmfaxTransportMedium_VMP {
  tSMVMPrxId rx;
  tSMVMPtxId tx;
} SMFAX_TRANSPORT_MEDIUM_VMP;
```

**Description**

This structure allows the user to specify that TiNG VMP endpoints are to be used instead of the basic stream and time-slot TDM system. Please read the appropriate TiNG documentation (see Appendix A: [1]) on how to allocate and configure these types.

6.1.3 SMFAX_TRANSPORT_MEDIUM_FMP

**Definition**

```c
typedef struct tSmfaxTransportMedium_FMP {
  tSMFMPrxId rx;
  tSMFMPtxId tx;
} SMFAX_TRANSPORT_MEDIUM_FMP;
```

**Description**

This structure allows the user to specify that TiNG FMP endpoints are to be used instead of the basic stream and time-slot TDM system. Please read the appropriate TiNG documentation (see Appendix A: [1]) on how to allocate and configure these types.
6.1.4 SMFAX_TRANSPORT_MEDIUM

**Definition**

ttypedef union tuSmfaxTransportMedium
{
    SMFAX_TRANSPORT_MEDIUM_TDM tdm;  /* in */
    SMFAX_TRANSPORT_MEDIUM_VMP vmp;  /* in */
    SMFAX_TRANSPORT_MEDIUM_FMP fmp;  /* in */
} SMFAX_TRANSPORT_MEDIUM;

**Description**

This union provides the user with a method for specifying one of many different forms of Prosody API endpoints.

tdm
See 6.1.1 on how to configure this.

vmp
See 6.1.2 on how to configure this.

fmp
See 6.1.3 on how to configure this.

6.1.5 SMFAX_DATA_TRANSPORT_PARMS

**Definition**

ttypedef struct tSmfaxDataTransportParms
{
    int type;
    SMFAX_TRANSPORT_MEDIUM *transport;
} SMFAX_DATA_TRANSPORT_PARMS;

**Description**

This structure allows for backward compatibility for when Prosody endpoints are not being used. However, it is highly recommended that developers become familiar with the use of Prosody endpoints.

type
This field can take one of the following values.

<table>
<thead>
<tr>
<th>Valid Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kSMFaxTransportType_Classic</td>
<td>Specify this value when endpoints are not used.</td>
</tr>
<tr>
<td>kSMFaxTransportType_TDM</td>
<td>Specify this value when TDM endpoints are used.</td>
</tr>
<tr>
<td>kSMFaxTransportType_VMP</td>
<td>Specify this value when VMP endpoints are used.</td>
</tr>
<tr>
<td>kSMFaxTransportType_FMP</td>
<td>Specify this value when FMP endpoints are used.</td>
</tr>
</tbody>
</table>

**transport**

This field must be set to NULL if type is set to kSMFaxTransportType_Classic.
Otherwise, this field must point to a valid SMFAX_TRANSPORT_MEDIUM structure. One of the member fields of the SMFAX_TRANSPORT_MEDIUM structure must reflect the choice made by setting the type field, which is explained above.
6.1.6 SMFAX_SESSION

Definition

typedef struct tSmfaxSession
{
    tSMModuleId module; /* in */
    tSMModuleId module_id; /* deprecated */
    tSMChannelId channel; /* in */
    SMFAX_DATA_TRANSPORT_PARMS data_transport; /* in */
    void *faxsession_inst; /* internal */
    SMFAX_USER_OPTIONS user_options; /* deprecated */
    tSM_INT exit_error_code; /* out */
    SMFAX_CAPS fax_caps; /* deprecated */
    SMFAX_GLOBAL_DATA *global_data; /* deprecated */
    SMFAX_UT32 fax_id; /* deprecated */
    SMFAX_TRACE_PARMS *trace_parms; /* in */
} SMFAX_SESSION;

Description

This is the primary interface structure to the Prosody FAX library.

module

The media processing resource identifier that channel was allocated on, as returned by sm_open_module(). See Appendix A: [1].

channel

A valid full duplex Prosody channel allocated using the Prosody API. See Appendix A: [1].

data_transport

Allows the use of Prosody endpoints instead of the basic stream and timeslot TDM system.

faxsession_inst

For internal library use only. Do not change.

exit_error_code

Upon termination of the fax session (see later) this field will give a numeric indication of the termination reason.

trace_parms

A pointer to a trace parameters structure. This allows tracing of the fax session creation process. If this pointer is not null trace is turned on, else it stays off. The fax_session field of trace_parms is currently ignored and should be set to null.

6.1.7 smfax_create_session

Prototype Definition

int smfax_create_session( SMFAX_SESSION *fax_session)

The argument fax_session is a pointer to a structure of type SMFAX_SESSION.

Description

This function is called to prepare the resources necessary for a fax session. Aspects such as terminal type and fax capabilities can be specified through a subsequent call to smfax_configure (setting SMFAX_USER_CONFIG and SMFAX_CAPABILITIES members).

The function can return one of four values. Upon failure the exit_error_code member of fax_session will provide a reason for the failure.
Returns

On success

kSMFaxStateMachineRunning

Fax session created successfully.

On failure

kSMFaxStateMachineTerminated

A session was created but the state machine failed to run. Check the value of exit_error_code.

kSMFaxNullPointer

Both module and module_id fields of SMFAX_SESSION are zero, or the channel field of SMFAX_SESSION is equal to kSMNullChannelId.

6.2 Fax session configuration

6.2.1 SMFAX_CAPABILITIES

Definition

typedef struct tSmfaxCapabilities {
  tSM_UT32  v17 :1; /* in/out */
  tSM_UT32  v29 :1; /* in/out */
  tSM_UT32  v27ter :1; /* in/out */
  tSM_UT32  fCappedDataRate :1; /* in */
  tSM_UT32  v8 :1; /* in */
  tSM_UT32  v34 :1; /* in */
  tSM_UT32  data_rate; /* in/out */
  tSM_UT32  min_data_rate /* in */
  tSM_UT32  ECM :1; /* in/out */
  tSM_UT32  ECMsize64 :1; /* in */
  tSM_UT32  MR2D :1; /* in/out */
  tSM_UT32  MMRT6 :1; /* in */
  tSM_UT32  Res200x200 :1; /* in */
  tSM_UT32  TIFFWidth :2; /* in */
  tSM_UT32  polling_mode :1; /* in/out */
  char    subscriber_id[kSMMaxSubscriberLen+1]; /* in */
  char    remote_id[kSMMaxSubscriberLen+1]; /* out */
} SMFAX_CAPABILITIES;

Description

This structure enables the user to specify the capabilities of the local fax terminal. The capabilities should reflect the features supported by the firmware installed on the media processing resource to be used for fax.

v17

Set this “C” bit-field to 1 to enable support for ITU-T V.17 modem. Leave as zero to disable. Please ensure that the necessary firmware modules have been loaded.
**v29**
Set this “C” bit-field to 1 to enable support for ITU-T V.29 modem. Leave as zero to disable. Please ensure that the necessary firmware modules have been loaded.

**v27ter**
Set this “C” bit-field to 1 to enable support for ITU-T V.27ter modem. Leave as zero to disable. Please ensure that the necessary firmware modules have been loaded.

**fCappedDataRate**
If V.17 has been enabled, setting this “C” bit-field to 1 will make V.17 7200 bps fall back to V.27 4800 bps bypassing V.29. If neither V.17 nor V.29 has been enabled, setting this “C” bit-field to 1 will cause a fax responder to indicate V.27ter fall-back mode and thus request for V.27 that only the 2400 bps rate be used.

**v8**
Set this “C” bit-field to 1 to enable support for the ITU-T V.8 procedures for starting sessions of data transmission over the public switched telephone network. Leave as zero to disable. No additional firmware is required for this feature. Required for V.34.

**v34**
Set this “C” bit-field to 1 to enable support for the ITU-T V.34 modem. Leave as zero to disable. Please ensure that the necessary firmware modules have been loaded. V.34 requires V.8 and ECM.

**data_rate**
This field can take one of the following valid values to allow the user to select the maximum speed at which the “calling” or “polled” session should first try to train. No additional firmware is required for this feature.

<table>
<thead>
<tr>
<th>Valid Value</th>
<th>Supporting Modem</th>
</tr>
</thead>
<tbody>
<tr>
<td>kSMFaxDataRate_2400</td>
<td>✓ V.2 7</td>
</tr>
<tr>
<td>kSMFaxDataRate_4800</td>
<td>✓ V.2 9</td>
</tr>
<tr>
<td>kSMFaxDataRate_7200</td>

<tr>
<td>kSMFaxDataRate_26400</td>
<td>✓ ✓ ✓</td>
</tr>
<tr>
<td>kSMFaxDataRate_28800</td>
<td>✓ ✓ ✓</td>
</tr>
<tr>
<td>kSMFaxDataRate_31200</td>
<td>✓ ✓ ✓</td>
</tr>
<tr>
<td>kSMFaxDataRate_33600</td>
<td>✓ ✓ ✓</td>
</tr>
<tr>
<td>kSMFaxDataRate_Default</td>
<td>✓ ✓ ✓</td>
</tr>
</tbody>
</table>

Specifying this value will instruct the library to use the best data rate available for the preferred modem.
On return, this field will hold one of the above values to indicate what baud rate was last used. This does not mean, however, that the entire fax call will use this rate. Typically this would be the highest data rate that is used in the fax call.

The “preferred modem” is the modem modulation agreed by both terminals at negotiation time. If both \texttt{MR2D} and \texttt{MMRT6} fields are disabled then the ITU-T T.30 recommendation default, ITU-T T.4 Modified Huffman encoding, is used.

\texttt{min\_data\_rate}

If this field is non-zero, return an error if the image transfer data rate ever drops below it.

\texttt{ECM}

Set this “C” bit-field to 1 to enable support for ITU-T T.30 Annex A “Error Correction Mode” and ITU-T T.4 Annex A. There are no explicit firmware requirements for this feature.

\texttt{ECMsize64}

Supported for fax receive only.

\texttt{MR2D}

Set this “C” bit-field to 1 to enable support for ITU-T T.4 Modified Read/Two-dimensional encoding of group 3 compliant TIFF data. Leave as zero to disable. No additional firmware required for this feature.

\texttt{MMRT6}

Set this “C” bit-field to 1 to enable support for ITU-T T.6 Modified Modified Read encoding of group 3 compliant TIFF data. Leave as zero to disable. No additional firmware required for this feature. If \texttt{MMRT6} is enabled then enabling \texttt{ECM} becomes mandatory.

\texttt{Res200x200}

Set this “C” bit-field to 1 to enable support for high-resolution images. Resolution increase is on the Y-axis. No additional firmware is required for this feature.

\texttt{TIFFWidth}

The value in this field is the preferred width of the facsimile image to be transmitted. This value is a request to the remote to comply with this width. However, the remote end does not have to agree to this specified width and is allowed to dictate the actual width to be used. No additional firmware is required for this feature.

<table>
<thead>
<tr>
<th>Constant Designation</th>
<th>Facsimile Image Width (pels)</th>
</tr>
</thead>
<tbody>
<tr>
<td>kSMFaxTIFFWidth_A4</td>
<td>1728</td>
</tr>
<tr>
<td>kSMFaxTIFFWidth_A3</td>
<td>2432</td>
</tr>
<tr>
<td>kSMFaxTIFFWidth_B4</td>
<td>2048</td>
</tr>
</tbody>
</table>

\texttt{polling\_mode}

If set to zero polling will not be negotiated and if set to one polling will be negotiated. The \texttt{polling\_mode} of \texttt{sel\_caps} member of \texttt{SMFAX\_NEGOTIATE\_CAPS\_PARMS}, after the negotiation will indicate if polling is negotiated or not.
**subscriber_id**
A twenty digit string, typically the digital subscriber identifier. Valid characters are [0~9, + and space character]. If there is no valid subscriber id, then it is advised that all twenty digits are set to the space character or the character ‘0’. Any unused digits should be set to the space character. No additional firmware is required for this feature.

**remote_id**
A twenty digit string, typically the digital subscriber identifier of the remote device. The Prosody Fax library will internally set this field at negotiation time. No additional firmware is required for this feature.

### 6.2.2 SMFAX_USER_CONFIG

#### Definition

define struct tUserConfig
{
  tSMIEEE32Bit754854Ffloat max_percent_badlines; /* in */
  tSM_UT32 max_consec_badlines; /* in */
  tSM_UT32 max_modem_fb; /* in */
  tSM_UT32 page_retries; /* in */
  tSM_INT fax_mode; /* in */
  tSM_UT32 idle_timeout; /* in */
  tSM_UT32 ecm_continue_to_correct : 1; /* in */
  tSM_UT32 drop_speed_on_ctc : 1; /* in */
} SMFAX_USER_CONFIG;

#### Description
This structure enables the user to control the way the library logic carries out the fax session.

**max_percent_badlines**
Set this value to indicate the acceptable percentage of erroneous scan lines in a received page. This field has meaning to a “Called” or “Polling” terminal. The floating-point value 1.0 denotes one hundred percent. A value of 0.05 would indicate five percent. This parameter is not relevant when using ECM mode. The value for this field must be chosen with care. If the value is set too low for a noisy connection then frequent re-transmissions will be required, potentially increasing the transmission time. However, in an application where document accuracy is paramount, a high value could compromise the legitimacy of the document.

**max_consec_badlines**
This field indicates the maximum number of consecutive erroneous scan lines to tolerate in a received page. This parameter is not relevant when using ECM mode. A library in “Called” or “Polling” mode would use max_percent_badlines and max_consec_badlines to rate the quality of the received document and subsequently request a retrain and/or retransmit.

**max_modem_fb**
This field allows the user to specify how many times a “Calling” or “Polled” terminal should retrain to a slower modem speed or modulation, should this be possible.

**page_retries**
The number of times a specific page should be retransmitted, should there be a need.
fax_mode
The terminal type of the local fax device. This field can take the following values.

<table>
<thead>
<tr>
<th>Terminal Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kSMFaxModeTransmitter</td>
<td>A fax terminal that makes a call and then sends one or more pages.</td>
</tr>
<tr>
<td>kSMFaxModeReceiver</td>
<td>A fax terminal that answers a call and receives one or more pages.</td>
</tr>
</tbody>
</table>

ilde_timeout
When there is a continuous inactivity for this duration the fax will be terminated. If set to zero not used. If set to a value less than 35000ms rounded up to 35000ms. Otherwise used as specified up to the default timer 3600000ms.

ecm_continue_to_correct
Set this “C” bit-field to 1 to allow the “Calling” or “Polled” terminal (during an ECM enabled fax call) to continue to re-transmit a partial page after the fourth partial page request (PPR). Leave as zero to continue with the next page (if any).

drop_speed_on_ctc
Set this “C” bit-field to 1 to allow the “Calling” or “Polled” terminal (during an ECM enabled fax call) to reduce the speed or modulation of the modem after the fourth PPR.

6.2.3 SMFAX_T38_SDP_OPTIONS
Definition
typedef struct tT38SDPOptions
{
    tSM_UT32 T38FaxVersion; /* in */
    tSM_UT32 T38FaxRateManagement; /* in */
    tSM_UT32 T38MaxBitRate; /* in */
    tSM_UT32 T38FaxUdpEC; /* in */
    tSM_UT32 T38FaxMaxDatagram; /* in */
    tSM_UT32 T38FaxMaxBuffer; /* in */
    tSM_UT32 T38FaxFillBitRemoval :1; /* in */
    tSM_UT32 T38FaxTranscodingMMR :1; /* in */
    tSM_UT32 T38FaxTranscodingJBIG :1; /* in */
} SMFAX_T38_SDP_OPTIONS;

Description
T.38 options negotiated during call set-up. See Appendix A: [5].

T38FaxVersion
This field can take one of four values.

<table>
<thead>
<tr>
<th>Value</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1998 ASN.1 syntax.</td>
</tr>
<tr>
<td>1</td>
<td>1998 ASN.1 syntax. TPKT not supported.</td>
</tr>
<tr>
<td>2</td>
<td>2002 ASN.1 syntax.</td>
</tr>
<tr>
<td>3</td>
<td>2002 ASN.1 syntax. V.34 and V.33 not supported.</td>
</tr>
</tbody>
</table>

T38FaxRateManagement
Two possible values, 1 for local TCF, and 2 for transferred TCF.
**T38MaxBitRate**
If negotiated, given priority over `SMFAX_CAPABILITIES.data_rate`.

**T38FaxUdpFEC**
Two possible values, 1 for UDP FEC and 2 for UDP Redundancy (UDP FEC is currently not supported).

**T38FaxMax Datagram**
Maximum T.38 payload in bytes.

**T38FaxMaxBuffer**
Not significant for Aculab T.38 IAF end-point implementation.

**T38FaxFillBitRemoval**
Not supported.

**T38FaxTranscodingMMR**
If enabled, `SMFAX_CAPS.MMRT6` and `SMFAX_CAPS.ECM` will be enabled.

**T38FaxTranscodingJBIG**
Not supported.

### 6.2.4 SMFAX_CONFIG_PARMS

**Definition**

```c
t typedef struct tSMfaxConfig
{
    SMFAX_SESSION *fax_session; /* in */
    SMFAX_CAPABILITIES *capabilities; /* in */
    SMFAX_USER_CONFIG *user_config; /* in */
    SMFAX_T38_SDP_OPTIONS *t38_sdp; /* in */
} SMFAX_CONFIG_PARMS;
```

**Description**

Once a fax session has been successfully created, this structure, along with its API function, `smfax_configure` should be used to configure the session.

**fax_session**
A pointer to a valid `SMFAX_SESSION` structure, as returned by `smfax_create_session`.

**capabilities**
A pointer to a valid `SMFAX_CAPABILITIES` structure, allocated and filled by the application.

**user_config**
A pointer to a valid `SMFAX_USER_CONFIG` structure, allocated and filled by the application.

**t38_sdp**
A pointer to a valid `SMFAX_T38_SDP_OPTIONS` structure, allocated and filled by the application. Must be present only for T.38 (kSMFaxTransportType_FMP or kSMFaxTransportType_EXT_T38), otherwise set to NULL pointer.
6.2.5 smfax_configure

**Prototype Definition**

```c
int smfax_configure(SMFAX_CONFIG_PARMS *fax_config_parms);
```

The argument `fax_config_parms` is a pointer to a structure of type `SMFAX_CONFIG_PARMS`.

**Description**

This function will configure the terminal capabilities, other user configurable options, and T.38 SDP values (only for a T.38 session).

**On success**

- `kSMFaxStateMachineRunning`: Fax session configured successfully.

**On failure**

- `kSMFaxBadParam`: Bad parameter was detected.
- `kSMFaxNullPointer`: Transport medium was T.38 but `t38_sdp` was set to null pointer.

6.3 Fax session negotiation

6.3.1 SMFAX_NEGOTIATE_CAPS_PARMS

**Definition**

```c
typedef struct tSmfaxNegotiateCapsParms {
    SMFAX_SESSION *fax_session; /* in */
    ACTIFF_PAGE_PROPERTIES *page_props; /* in/out */
    SMFAX_CAPABILITIES *sel_caps; /* in/out */
    tSM_UT32 detection_timeout; /* in */
    tSM_UT32 negotiation_timeout; /* in */
} SMFAX_NEGOTIATE_CAPS_PARMS;
```

**Description**

Once a fax session has been successfully created and configured, this structure, along with its API function, `smfax_negotiate_caps` can be used to progress the fax session through the negotiation phase (ITU-T T.30 phase B).

- `fax_session`: A pointer to a valid `SMFAX_SESSION` structure, as returned by `smfax_create_session`.
- `page_props`: This member must be allocated by the application, and the address passed in. If this member is not required, it must be set to NULL. If used after negotiation this member can be queried for the agreed group 3 compliant TIFF image metrics (information such as image encoding and image resolution). The application must set this to a valid pointer or NULL.
- `sel_caps`: This member must be allocated by the application, and the address passed in. If this member is not required, it must be set to NULL. If used, after the negotiation it will be set to reflect the capabilities negotiated by the two fax terminals. `polling_mode` member will be non-zero if a polling or polled session was negotiated.
**detection_timeout**

Only supported by the originator. If set a fax tone or a V.21 modem signal from the other terminal prior to expiry will cancel this. If expired the fax will be terminated. The valid range of values starts from 5000ms. If set to zero unused. Values less than 5000 are rounded up to 5000. When used to stimulate call clearance in time shorter than normal T.30 35s timeout, T1 will remain at its standard setting. When used with value greater than normal T1 to accommodate peer system that plays voice announcement prior to switching to fax, initial T1 will be set to this detection timeout value.

**negotiation_timeout**

Introduced due to the limitation that T1 would be cancelled after any valid V.21 HDLC packet, leading to lengthy unsuccessful negotiations. If expired the fax will be terminated. The valid range of values is 60000ms to the default timer 3600000ms. If set to zero unused. Values less than 6000 are rounded up to 60000.

### 6.3.2 smfax_negotiate_caps

**Prototype Definition**

```c
int smfax_negotiate_caps(SMFAX_NEGOTIATE_CAPS_PARMS *fax_negParms_);
```

The argument `fax_negParms_` is a pointer to a structure of type `SMFAX_NEGOTIATE_CAPS_PARMS`.

**Description**

This function will progress the fax session through the negotiation phase (ITU-T T.30 phase B). If the function returns successfully then the `polling_mode` member of `sel_caps` member of SMFAX_NEGOTIATE_CAPS_PARMS should be interrogated before the next API function is called, the value of `polling_mode` will dictate which function is to be called next).

If the value of `polling_mode` is zero then a non-polling/non-polled fax session has been established. This would be the expected value if the `polling_mode` member of SMFAX_CAPABILITIES was set to zero in `smfax_configure`.

A polling/polled fax session has been established if the value of `polling_mode` is non-zero. This is expected if the value of `polling_mode` member of SMFAX_CAPABILITIES was set to non-zero in `smfax_configure`.

**NOTE**

For more on polling and polled fax sessions see Fax On Demand.

<table>
<thead>
<tr>
<th>polling_mode</th>
<th>fax_mode</th>
<th>Next API function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>kSMFaxModeTransmitter</td>
<td><code>smfax_tx_page_process</code></td>
</tr>
<tr>
<td>1</td>
<td>kSMFaxModeTransmitter</td>
<td><code>smfax_rx_page_process</code></td>
</tr>
<tr>
<td>0</td>
<td>kSMFaxModeReceiver</td>
<td><code>smfax_rx_page_process</code></td>
</tr>
<tr>
<td>1</td>
<td>kSMFaxModeReceiver</td>
<td><code>smfax_tx_page_process</code></td>
</tr>
</tbody>
</table>
Returns

On success

\[ \text{kSMFaxStateMachineRunning} \]

Negotiation was generally a success. The state machine awaits the next command.

On failure

\[ \text{kSMFaxStateMachineTerminated} \]

Unsuccessful negotiation occurred. The state machine has been stopped. Check the exit_error_code member of SMFAX_SESSION for a reason for this failure.

6.4 Fax page processing

6.4.1 SMFAX_TX_PAGE_PROCESS_PARMS

Definition

```c
typedef struct tSmfaxTxPageProcessParms {
    SMFAX_SESSION *fax_session; /* in */
    tSM_INT is_last_page; /* in */
    SMFAX_CAPABILITIES *sel_caps; /* in/out */
    tSM_UT32 page_timeout; /* in */
} SMFAX_TX_PAGE_PROCESS_PARMS;
```

Description

Once the negotiation has been successful, this structure can be used with smfax_tx_page_process to transmit a previously loaded fax page using smfax_load_page. Both transmission and receive API functions* will progress the fax session through the message procedure, ITU-T T.30 phase C.

**fax_session**

A pointer to a valid SMFAX_SESSION structure as returned by smfax_create_session.

**is_last_page**

This member can be assigned one of two values. A fax session undertaking transmission will use the value of this member to control what handshake signals are sent once the fax page data has been transmitted.

<table>
<thead>
<tr>
<th>is_last_page</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kSMFaxNotLastPage</td>
<td>The page to be transmitted is not the last page. The transmission API function will return allowing the API user to send more pages. This also means that another page must follow the current page.</td>
</tr>
<tr>
<td>kSMFaxLastPage</td>
<td>The page to be transmitted is the last page. The transmission API function will return once the terminate message has been sent. No further pages can be sent with this fax session.</td>
</tr>
</tbody>
</table>

**sel_caps**

This member must be allocated by the application, and the address passed in. If this member is not required, it must be set to NULL. If used, after the page transmission it will be set to reflect the capabilities used by the two fax terminals.
**page_timeout**

In milliseconds, the maximum time allowed for a continuous image data transmission or reception. If expired, the fax will be terminated. The valid range of values is 60000ms to the default timer 3600000ms. If set to zero unused. Values less than 60000 are rounded up to 60000. Any fax control signal restarts this timer at the start of the image data transmission or reception.

6.4.2 **smfax_tx_page_process**

**Prototype Definition**

```c
int smfax_tx_page_process(SMFAX_TX_PAGE_PROCESS_PARMS *fax_pp_parms_);
```

The argument `fax_pp_parms_` is a pointer to a structure of type `SMFAX_TX_PAGE_PROCESS_PARMS`.

**Description**

This function will progress the fax session through the message procedure phase, ITU-T T.30 phase C.

Prior to invocation of this function, an appropriate Group 3 compliant TIFF file page should have been loaded using `smfax_load_page`. After successful negotiation, the `TIFFWidth` field of the `sel_caps` member of `SMFAX_NEGOTIATE_CAPS_PARMS` structure should be queried to discover what image width has been agreed. A group 3 compliant TIFF file of such proportions should then be loaded.

The page loading must be done prior to calling this API function.

The member `is_last_page` should indicate the intention to send more pages or not, following the current page.

**Returns**

- **kSMFaxStateMachineRunning**: Transmission was a success. The state machine is waiting for the next command. Typically, this API function would be called again with the next page to be sent.

- **kSMFaxStateMachineTerminated**: Transmission may have been a success. No more invocations of the transmission or negotiation API can be made.

If the latest page to be sent was the last page then, on successful transmission, the transmission API function will return with **kSMFaxStateMachineTerminated**. However, the return of this code does not imply that the transmission was a success. The `exit_error_code` member of `fax_session` should be interrogated for an explanation of why this API function returned.

A perfect transmission (indicated by peer fax sending T.30 MCF) will result in `exit_error_code` of **kSMDCNNormal**

A successful but imperfect transmission (indicated by peer fax sending T.30 RTP) will result in `exit_error_code` of **kSMDCNPageQualityPoor**

If after several retries/renegotiations (indicated by peer fax sending T.30 RTN) required quality still not achieved, a failed transmission will result in `exit_error_code` of **kSMDCNPageRetryExceeded**
6.4.3 SMFAX_RX_PAGE_PROCESS_PARMS

**Definition**

```c
typedef struct tSmfaxRxPageProcessParms {
    SMFAX_SESSION *fax_session; /* in */
    ACTIFF_PAGE_HANDLE *page_handle; /* in/out */
    tSM_INT renegotiate; /* out */
    ACTIFF_PAGE_PROPERTIES *page_props; /* in/out */
    SMFAX_CAPABILITIES *sel_caps; /* in/out */
    tSM_UT32 page_timeout; /* in */
} SMFAX_RX_PAGE_PROCESS_PARMS;
```

**Description**

Once negotiated, this structure can be used with `smfax_rx_page_process` to receive a fax page. Both transmission and receive API functions* will progress the fax session through the message procedure, ITU-T T.30 phase C.

- **fax_session**: A pointer to a valid `SMFAX_SESSION` structure as returned by `smfax_create_session`.
- **page_handle**: The address of an `ACTIFF_PAGE_HANDLE` type allocated by the user application. This will be required by `smfax_close_page` after the page is stored using `smfax_store_page`.
- **renegotiate**: This member will indicate whether or not the negotiation API must be called again. A non-zero value indicates that the negotiation API i.e. `smfax_negotiate_caps` must be called, a zero value indicates that the negotiation API must not be called.
- **page_props**: This member must be allocated by the application, and the address passed in. If this member is not required, it must be set to NULL. For each page received this member can be queried for information such as the number of bad lines and the negotiated page properties.
- **sel_caps**: This member must be allocated by the application, and the address passed in. If this member is not required, it must be set to NULL. If used, after the page reception it will be set to reflect the capabilities used by the two fax terminals.
- **page_timeout**: In milliseconds, the maximum time allowed for a continuous image data transmission or reception. If expired the fax will be terminated. The valid range of values is 60000ms to the default timer 3600000ms. If set to zero unused. Values less than 60000 are rounded up to 60000. Any fax control signal restarts this timer at the start of the image data transmission or reception.

### 6.4.4 smfax_rx_page_process

**Prototype Definition**

```c
int smfax_rx_page_process(SMFAX_RX_PAGE_PROCESS_PARMS *fax_pp_parms);
```

The argument `fax_pp_parms` is a pointer to a structure of type `SMFAX_RX_PAGE_PROCESS_PARMS`. 
Description
This function will progress the fax session through the message procedure phase, ITU-T T.30 phase C.

If the return code of this function indicates that the state machine is still running, then this API function must be called again. The remote terminal has more pages to send to this terminal.

The `renegotiate` member of `SMFAX_RX_PAGE_PROCESS_PARM` must be interrogated following the API function return. The `renegotiate` member will indicate whether or not the negotiation API must be called again (T.30 EOM). The API user must call `smfax_store_page` to store recently received page. After storing the page call `smfax_negotiate_caps` if `renegotiate` is non zero.

On the occasions where retraining was required due to insufficiently good page quality (T.30 RTN) the fax library will retrain without user intervention. In that case the `smfax_rx_page_process` will return once a page has been successfully received (note the original rejected "too poor quality" page will not be available to application and not included in page count).

Returns
- `kSMFaxStateMachineRunning`: Reception was a success. The state machine awaits the next command.
- `kSMFaxStateMachineTerminated`: No more invocations of the reception or negotiation API can be made with this fax session. Check the exit/error code to ascertain if the last reception was a success or not.

Notes – when the return code is `kSMFaxStateMachineTerminated` an application normally would only decide to store a page if page is complete and peer fax has received confirmation of successful (but possibly imperfect) transmission. This is the case for the following exit/error codes:

- `kSMFaxDCNNormal`
- `kSMFaxDCNNoDCNFromRemote`
- `kSMFaxDCNPageQualityPoor`

However some applications may wish to allow access to partially transferred pages, this is possible in non-ECM mode when the `page_props` field `image_length` is non-zero. It can be determined whether ECM mode was used through interrogation of the `sel_caps` field `ECM`.

6.4.5 `SMFAX_RX_PAGE_PROCESS_WITH_RETRY_TIMEOUT_PARM`

Definition
```c
typedef struct tSmfaxRxPageProcessWithRetryTimeoutParsm {
    SMFAX_SESSION *fax_session; /* in */
    ACTIFF_PAGE_HANDLE *page_handle; /* in/out */
    tSM_INT renegotiate; /* out */
    ACTIFF_PAGE_PROPERTIES *page_props; /* in/out */
    SMFAX_CAPABILITIES *sel_caps; /* in/out */
    tSM_UINT page_timeout; /* in */
    tSM_UINT total_page_timeout; /* in */
} SMFAX_RX_PAGE_PROCESS_WITH_RETRY_TIMEOUT_PARMS;
```
Description
Once negotiated, this structure can be used with `smfax_rx_page_process_with_retry_timeout` to receive a fax page. This structure is the same as `SMFAX_RX_PAGE_PROCESS_PARMS` except it has one additional member.

`total_page_timeout`
In milliseconds, the maximum elapsed time allowed for a page reception including retry attempts. If set to zero unused. If expired, the fax will be terminated. See Appendix E.2 for more details.

6.4.6 `smfax_rx_page_process_with_retry_timeout`

Prototype Definition
```c
int smfax_rx_page_process_with_retry_timeout(
    SMFAX_RX_PAGE_PROCESS_WITH_RETRY_TIMEOUT_PARMS *fax_ppparms);
```

The argument `fax_ppparms` is a pointer to a structure of type `SMFAX_RX_PAGE_PROCESS_WITH_RETRY_TIMEOUT_PARMS`.

Description
This function is identical to `smfax_rx_page_process` except an additional `total_page_timeout` parameter is provided. For more details on use of this timeout, see Appendix E.2.

6.5 Page Manipulation

6.5.1 `SMFAX_PAGE_ACCESS_PARMS`

Definition
```c
typedef struct tSmfaxPageAccessParms
{
    SMFAX_SESSION *fax_session; /* in */
    ACTIFF_FILE *actiff; /* in */
    ACTIFF_PAGE_PROPERTIES *page_props; /* deprecated */
    ACTIFF_PAGE_HANDLE *page_handle; /* in/out */
    tSM_UT32 page_index; /* in */
} SMFAX_PAGE_ACCESS_PARMS;
```

Description
This structure allows the retrieval of an individual page from a Group 3 compliant TIFF into an Aculab proprietary type, the `ACTIFF_PAGE_HANDLE`. It also allows a page held in an instance of the Aculab proprietary type to be stored to a Group 3 compliant TIFF.

- `fax_session`
  A pointer to a valid fax session, as returned by the fax session creation API.

- `actiff`
  A valid pointer to an `ACTIFF_FILE` that has been opened for read or write, as returned by the appropriate Aculab Image Processing API. See Appendix A.2.

- `page_handle`
  A valid pointer to an `ACTIFF_PAGE_HANDLE`. This field is set by `smfax_load_page` and `smfax_rx_page_process`, and used only by `smfax_close_page`
• **page_index**
  
  The index in the Group 3 compliant TIFF of the page in which we are interested. Page indexing begins at 0. The first page in a TIFF has a page index of 0 (zero). In a TIFF with \( N \) pages the last page has a page index of \((N-1)\).

### 6.5.2 smfax_load_page

**Prototype Definition**

```c
int smfax_load_page(SMFAX_PAGE_ACCESS_PARMS *fax_pa_parms_);
```

The argument `smfax_load_page` is a pointer to a structure of type `SMFAX_PAGE_ACCESS_PARMS`. See `SMFAX_PAGE_ACCESS_PARMS`.

**Description**

This function allows the retrieval of an individual page from a Group 3 compliant TIFF into an Aculab proprietary type, the `ACTIFF_PAGE_HANDLE`.

The `page_handle` member of `fax_pa_parms_` must point to an `ACTIFF_PAGE_HANDLE` that has been initialised to zero.

The `actiff` member of `fax_pa_parms_` should point to an `ACTIFF_FILE` that has access to the desired Group 3 compliant TIFF, and has been opened for reading. See Aculab Image Processing API, Appendix A.[2]

The page to be loaded will be indicated by the `page_index` member.

This function is typically called when a TIFF page is to be transmitted to the remote fax device. It is imperative that this function is called prior to the page transmission API function. The application must wait for the transmission API function to return before calling this API function on the next page to be sent, if any.

**Returns**

**On success**

`kSMFaxPageOK`  

The specified page has been successfully loaded into the `ACTIFF_PAGE_HANDLE`.

**On failure**

`kSMFaxNullPointer`  

The specified fax session pointer is null.

`kSMFaxPageReadError`  

The specified `ACTIFF_FILE` pointer is invalid.

`kSMFaxPageNotStored`  

The specified page was not found.

`kSMFaxDCNRemoteIncompatible`  

The negotiation phase failed (or was not executed) or the system could not allocate memory for internal use.

`kSMFaxPageWrongWidth`  

The specified page does not match the agreed width.

`kSMFaxPageResourceError`  

Some internal fax state machine process yielded invalid data.

`kSMFaxResourceAllocFailed`  

The system could not allocate memory resource for an internal type.
6.5.3 smfax_store_page

Prototype Definition

```c
int smfax_store_page(SMFAX_PAGE_ACCESS_PARMS *fax_pa_parms);
```

The argument `fax_pa_parms` is a pointer to a structure of type `SMFAX_PAGE_ACCESS_PARMS`.

Description

This function allows the storage of a received fax image from the Aculab proprietary type (ACTIFF_PAGE_HANDLE) to a Group 3 compliant TIFF.

The `page_handle` member of `SMFAX_PAGE_ACCESS_PARMS` should point to the same location as the `page_handle` member of `SMFAX_RX_PAGE_PROCESS_PARMS`, as returned by the reception API function.

The `actiff` member of `fax_pa_parms` should point to an ACTIFF_FILE that has access to the desired Group 3 compliant TIFF, and has been opened for writing. See Aculab Image Processing API, Appendix A:[2].

This function is typically called when this fax device has received a fax image. This function need not be called straight after the reception API has returned. It can be called once the final fax page has been received, providing each received page uses a separate ACTIFF_PAGE_HANDLE.

Returns

On success

- `kSMFaxPageOK` The specified page has been successfully stored from the ACTIFF_PAGE_HANDLE to the specified Group 3 TIFF file.

On failure

- `kSMFaxNullPointer` The specified fax session pointer is null
- `kSMFaxPageWriteError` The specified ACTIFF_FILE pointer is invalid.
- `kSMFaxPageReadError` The specified page handle is a read only object.
- `kSMFaxPageNotStored` A null page handle was specified and the page was not stored.

6.6 Post fax session cleanup

6.6.1 smfax_close_page

Prototype Definition

```c
int smfax_close_page(ACTIFF_PAGE_HANDLE *page_handle);
```

The argument `page_handle` is a pointer to a valid ACTIFF_PAGE_HANDLE.

Description

This function will release any resources taken up by either a fax image that has been received or a fax image that was loaded from persistent storage for transmission.

Typically, this function should be called once there is no longer any use for the specified ACTIFF_PAGE_HANDLE.
Returns

On success

kSMFaxPageOK

The resources have been successfully released.

On failure

kSMFaxPageResourceError

Internal processing error. A null temporary ACTIFF_FILE associated with this page handle.

kSMFaxPageReadError

The page handle is marked as read only but there is no reader object associated with it.

kSMFaxNullPointer

A null page handle was specified.

Other

Error codes from the Prosody Fax Image Processing API error code set should be expected.

6.6.2 smfax_close_session

Prototype Definition

int smfax_close_session(SMFAX_SESSION *fax_session_);

The argument fax_session_ must be a valid pointer to a previously created fax session, as returned by the session creation API function.

Description

This function will release any resources taken up by the fax session instance that is specified. The fax API user must avoid calling this function while the specified fax session is still in use; for example, if the page transmission or page reception API is still operating on this fax session.

Once a fax session is closed in this way, no more API calls can be made on this fax session.

Returns

On success

0

The resources taken up by the fax session have been released.

On failure

kSMFaxNullPointer

The specified fax session is invalid.

kSMFaxERRORApiInCorrect

Returned if the specified fax session’s state machine is still operating, meaning that the fax session is still in use.
6.7 Fax session interruption

6.7.1 smfax_rude_interrupt

Prototype Definition
int smfax_rude_interrupt(SMFAX_SESSION *fax_session);

The argument fax_session_ must be a valid pointer to a previously created fax session, as returned by the session creation API function.

Description
This API function can be used to bring the internal fax state machine to a halt. Upon invocation of this function, a synchronous fax API function would be expected to return promptly.

This API function is typically called when the call control API has indicated that there has been a remote disconnect event for this fax call.

This function may be called from a separate thread while the specified fax session is in use by one of the page processing or the negotiation API functions.

Returns
On success
0
The interrupt was successfully issued.

On failure
kSMFaxNullPointer
If the fax session associated with argument sfs_ is null/invalid. Perhaps it has been closed or was never created.

Other
Return values of operating system dependent EVENT functions should be expected.

6.7.2 smfax_polite_interrupt

Prototype Definition
int smfax_polite_interrupt(SMFAX_SESSION * fax_session_);

The argument fax_session_ must be a valid pointer to a previously created fax session, as returned by the session creation API function.

Description
This API function can be used to bring the internal fax state machine to a graceful halt. Upon invocation of this function, a synchronous fax API function may return promptly.

This function is typically called when the return of the negotiation API function indicates that a different type of fax session has been established to that which is desired.

For example, a ‘Called’ fax session may have been indicated at session creation but the remote terminal instead has negotiated a ‘Polling’ mode fax session.

In this situation, this API function would be invoked prior to calling a blocking API function such as smfax_rx_page_process or smfax_tx_page_process.
This function may be called from a separate thread while the specified fax session is in use by one of the page processing or negotiation API functions.

**Returns**

**On success**

0

The interrupt was successfully issued.

**On failure**

kSMFaxNullPointer

The fax session associated with argument \textit{sfs} is null or invalid. Perhaps it has been closed or was never created.

**Other**

Return values of operating system dependent \texttt{EVENT} functions should be expected.

### 6.8 Fax activity trace – debugging

#### 6.8.1 SMFAX_TRACE_PARMS

**Definition**

```c
typedef struct tSmfaxTraceParms
{
    SMFAX_SESSION    *fax_session;  /* in */
    SMFAX_STATUS     *fax_status;   /* unused */
    tSM_INT          timeout;       /* unused */
    BFILE            *log_file;     /* in */
    tSM_UT32         trace_level;   /* in */
} SMFAX_TRACE_PARMS;
```

**Description**

This structure allows the manipulation of fax activity trace.

**\texttt{fax\_session}**

A valid fax session object as returned by the fax session creation API function.

**\texttt{log\_file}**

A valid \texttt{BFILE} object. As returned by the appropriate \texttt{BFILE} API. See Appendix A[1]. The \texttt{BFILE} object will typically be associated with a persistent file on a mass storage subsystem (i.e. a hard disk drive).
**trace_level**

Is a mask which filters the type of trace going to log_file. This field can be a disjunction (bit-wise OR) of predefined constants found in the API header file.

<table>
<thead>
<tr>
<th>Constant Designation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>TRACE_DEBUG</td>
<td>Low-level information. For developer use.</td>
</tr>
<tr>
<td>TRACE_WARNING</td>
<td>Incidents that may cause mischief but need not terminate the fax session.</td>
</tr>
<tr>
<td>TRACE_ERROR</td>
<td>Incidents that will bring the fax session to an end.</td>
</tr>
<tr>
<td>TRACE_STATE_MACHINE</td>
<td>Internal state machine activity.</td>
</tr>
<tr>
<td>TRACE_STATES</td>
<td>Report of incoming and outgoing handshake messages.</td>
</tr>
<tr>
<td>TRACE_API_CALLS</td>
<td>Report of all invoked API calls.</td>
</tr>
<tr>
<td>TRACE_IMAGE_DATA</td>
<td>Trace image data for some modes</td>
</tr>
<tr>
<td>TRACE_ALL</td>
<td>Trace everything.</td>
</tr>
</tbody>
</table>

For example, to trace handshake messages, warnings and errors only; this field may be set as follows:

```c
SMFAX_TRACE_PARMS stp;
...
...
stp.trace_level = TRACE_STATES | TRACE_WARNING | TRACE_ERROR;
```

The API, see Appendix A[1], does not tie an API user down to tracing to a hard disk, the API is extensible enough to allow a user to overload specific functions to associate the 'file' with any storage medium they may require. So, for example, read and write may be performed on an IP socket.

On an Aculab Prosody Fax enabled system that may perform moderate to high fax channel counts it is advised that the storage medium to which the trace will be directed has a low latency.

### 6.8.2 smfax_trace_on

**Prototype Definition**

```c
int smfax_trace_on(SMFAX_TRACE_PARMS *fax_trace_parms);
```

The argument `fax_trace_parms_` must be a valid pointer to a `SMFAX_TRACE_PARMS` structure.

**Description**

In the event where a fax session is not responding in the way it is expected to, it may be necessary to inspect what is going on underneath the API calls. In such an event, invoking `smfax_trace_on` will stream textual information to the file associated with `SMFAX_TRACE_PARMS.log_file`.

The `fax_session` field must point to a valid `SMFAX_SESSION` object as returned by the fax session creations API. This needs to be the fax session for which the user intends to obtain trace.

Set the `trace_level` field, as previously described, to specify the trace filter level. The filter level need not remain the same throughout the lifetime of a fax session. Should a different level of detail be required, then this API can be called again with a different value for the `trace_level` field.
6.8.3 smfax_trace_off

Prototype Definition
int smfax_trace_off(SMFAX_TRACE_PARMS * fax_trace_parms_);
The argument fax_trace_parms_ must be a valid pointer to a SMFAX_TRACE_PARMS structure.

Description
If fax activity trace is no longer required before the end of the fax session, then this function can be called to stop trace from going to the file associated with log_file.
This API function is not mandatory, thus it need not be called prior to fax session clear up.

Returns
On success
0
The trace activation was a success.

On failure
kSMFaxNullPointer
The field fax_session and/or log_file is null.

Other
The BFILE API return codes should be expected.

6.9 Miscellaneous

6.9.1 smfax_error_to_text

Prototype Definition
char * smfax_error_to_text(int err_);
The argument err_ must be the error code that is to be mapped to a string literal.

Description
This function returns a string literal for the specified integer error code. The integer argument should typically be the exit_error_code field of SMFAX_SESSION.
The string literal set is limited to the error codes belonging to the fax library. String literals for Prosody error codes are not provided.
Returns
On success
Null terminated string
The error code is in the fax library error code set.

On failure
NULL
The error code scope is outside the fax library.

6.9.2 smfax_get_msgs

Prototype Definition

int smfax_get_msgs(SMFAX_GET_MSGS_PARMS *get_msg)

Where the parameter get_msg is a pointer to the following type:

typedef struct tSmfaxGetMsgsParms {
   SMFAX_SESSION               *fax_session;
   SMFAX_MSGS                  *msgs;
} SMFAX_GET_MSGS_PARMS;

Inputs

fax_session is a pointer to a structure as described in the “Fax Session Initialisation” section.

Outputs

msgs on return may point to a primitive linked-list of SMFAX_MSGS.

The member msgs is a pointer to the following type:

typedef struct tSmfaxMsgs {
   int msg_len;
   unsigned char                *msg;
   unsigned char                fSent;
   struct tSmfaxMsgs            *next;
} SMFAX_MSGS;

Description

The fields in SMFAX_MSGS are all output fields and have the following meanings.

msg_len
The length, in octets, of the array of unsigned chars pointed to by msg.

msg
A pointer to an array of unsigned chars that holds one frame of the handshake octets exchanged during the specified fax call. The third array element is the facsimile control field. However, if this element holds a value of zero then this may be an ECM message and the fourth element, if any, should be treated as the facsimile control field. The ‘C’ header file defs.h, found in the Aculab fax distribution, contains constants that relate the hexadecimal number of the facsimile control field to ITU-T T.30 acronyms.

fSent
If set to non-zero, indicates that the message in msg was transmitted by this terminal. Otherwise the message in msg was received from the remote fax terminal.
next
If there were more messages exchanged during the lifetime of this fax call then next will point to the next message to have been exchanged.

This function will typically be called following a call to the negotiation function(s). It can also be called following calls to the page exchange functions, smfax_rx_page_process() and smfax_tx_page_process().

Prior to the very first call to smfax_get_msgs(), SMFAX_GET_MSGS_PARMS.msgs must point to NULL.

It must be noted that one or more messages may exhibit the same facsimile control field. This is not an error, but may be an indication that the message was sent more than once during the lifetime of this fax call.

This function may return with success even though the message list is empty. This will happen if at the time this function was called there were no messages exchanged.

Returns

0 If the call was successful.
Other Error codes for system dependent mutex functions should be expected.

6.9.3 smfax_version

Prototype Definition
const char* smfax_version(SMFAX_VERSION_PARMS *verparms_)
Where the parameter verparms_ is a pointer to the following type:

typedef struct tSmfaxVersionParms
{
    char version_str[VERSION_STR_LEN];
} SMFAX_VERSION_PARMS;

Description
This function allows a user to report the version number of the Aculab Prosody Fax API programmatically. The version number is returned as a null terminated string.

The argument verparms_ has been included for future expansion.

Returns
The Fax API version number as a null terminated string.
7 Fax On Demand – Polled Mode Fax

In this mode of operation the fax terminal making the call intends to receive one or more pages of fax and the answering fax terminal will typically send one or more pages.

This facilitates fax services such as sports results and weather reports.

7.1 Polling fax terminal

The polling fax terminal is the fax terminal that makes the call and receives one or more pages of fax. The Aculab Prosody Fax library can operate in this mode.

To achieve a polling fax terminal an API user can do the following:

Establish a call using the Aculab call control API, see Appendix A:[4]. Allocate a full duplex Prosody channel, see Appendix A:[1]. The established call is switched to the Prosody channel, using Aculab switch API, see Appendix A: [3]. Invoke `smfax_create_session` then `smfax_configure` specifying the necessary parameters. In particular, the `fax_mode` field of `SMFAX_USER_CONFIG` must be set to `kSMFaxModeTransmitter` and the `polling_mode` field of `SMFAX_CAPABILITIES` should be set to a value of 1. Next invoke `smfax_negotiate_caps`.

If negotiation is successful and the value of the `sel_caps->polling_mode` field of `SMFAX_NEGOTIATE_CAPS_PARMS` is non-zero, then `smfax_tx_page_process` or `smfax_rx_page_process_with_retry_timeout` should be called appropriately to receive one or more pages of fax.

If the negotiation was a success but the value of `polling_mode` is zero, then either a page must be loaded and sent with `smfax_tx_page_process`, or `smfax_polite_interrupt` should be called, followed by a call to `smfax_tx/rx_page_process` or `smfax_rx_page_process_with_retry_timeout`, in order to send a disconnect fax message to the remote fax terminal and bring the fax session to an end.

Clear up used resources by calling `smfax_close_page` and `smfax_close_session` appropriately.

7.2 Polled fax terminal

The polled fax terminal is the fax terminal that answers a call and sends one or more pages of fax. The Aculab Prosody Fax library can operate in this mode.

To achieve a polled fax terminal an API user can do the following:

Establish a call using the Aculab call control API, see Appendix A:[4]. Allocate a full duplex Prosody channel, see Appendix A:[1]. The established call is switched to the Prosody channel, using Aculab switch API, see Appendix A: [3]. Invoke `smfax_create_session` then `smfax_configure` specifying the necessary parameters. In particular, the `fax_mode` field of `SMFAX_USER_OPTIONS` must be set to `kSMFaxModeReceiver` and the `polling_mode` field of `SMFAX_CAPABILITIES` should be set to a value of 1. Next invoke `smfax_negotiate_caps`.

If negotiation is successful and the value of the `sel_caps->polling_mode` field of `SMFAX_NEGOTIATE_CAPS_PARMS` is non-zero, then `smfax_tx_page_process` should be called appropriately to send one or more pages of fax.

If the negotiation was a success but the value of `polling_mode` is zero, then either this terminal must call `smfax_rx_page_process` or
smfax_rx_page_process_with_retry_timeout to receive a fax, or
smfax_polite_interrupt should be called, followed by a call to
smfax_tx/rx_page_process or smfax_rx_page_process_with_retry_timeout, in order
to send a disconnect fax message to the remote fax terminal and bring the fax
session to an end.

Clear up used resources by calling smfax_close_page and smfax_close_session.

Appendix B: Exit and Return Codes

These are the values that the exit_error_code field of SMFAX_SESSION may take upon fax termination.

Of the error codes described below, the kSMFaxDCN codes can be found in the header file smfaxapi.h.

<table>
<thead>
<tr>
<th>Exit Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>kSMFaxDCNNormal</td>
<td>Fax session came to an end with no failures.</td>
</tr>
<tr>
<td>kSMFaxDCNCNGFailed</td>
<td>Generation of the CNG tone failed.</td>
</tr>
<tr>
<td>kSMFaxDCNCTCMaxTries</td>
<td>ECM TX: The CTC command was sent 3 times following the fourth received PPR in the current sequence.</td>
</tr>
<tr>
<td>kSMFaxDCNCTCNotEnabled</td>
<td>ECM TX: The option to continue to correct is disabled. Therefore ending the call after the fourth PPR is received.</td>
</tr>
<tr>
<td>kSMFaxDCNNoDCNFromRemote</td>
<td>RX sent and repeated MCF for the final page, but did not receive DCN.</td>

Appendix C: Firmware

The table below details the firmware modules that are necessary to send and receive faxes under Prosody TiNG. The common files must be downloaded in order for fax to function regardless of the mode of operation.

For descriptions of the firmware modules listed below please see Appendix A: [1]. It is recommended that all receive or transmit files are downloaded so as to ensure compatibility with the majority of fax machines.

### C.2 Firmware modules specific to V.34 and Fax over RTP

When V.34 functionality is desired (also implies use of V.8) the firmware modules v34hd, ansam, prefsuf and fskasyrx must be loaded on to all the applicable media processing resources. Unlike the V.27, V.29 and V.17 implementations there is only one firmware module for V.34 which implements both the receiver and transmitter. When the transport medium is VMP then the firmware modules vmptx, vmprx will be required.

### C.3 Additional firmware modules specific to enabling T.38

In addition to the modules listed above, the enhanced media processing resources on Prosody X cards must be loaded with the firmware modules ifprx, ifptx, fmpx, fmpx to enable them to perform T.38 endpoint facsimile. For applications that will be doing a re-invite, vmprx and vmptx will also be required.
Appendix D: Deprecated functions and data structures

Some API calls from earlier versions of faxlib are now deprecated, they are listed here for reference. For new applications the, more general, API calls in API call descriptions should now be used, for example invoking smfax_configure is more flexible and preferred to using the deprecated fields in smfax_create_session.

D.1 Deprecated functions

Appendix E: Use Of Timeouts

A number of timeout facilities are provided for fax sessions. This appendix gives more information on their use.

E.1 Fax Origination

For a fax originator, it might not be known in advance if the peer entity being connected is actually a fax. The detection_timeout facility that can be set in smfax_negotiate_caps allows an application to clear down a call if there is no sign of a fax machine responding (with a fax tone or V.21 data) within the specified period.

Once it has been determined there is a peer fax responding entity, the maximum elapsed time for the negotiation phase can be limited using the negotiation_timeout (again set in smfax_negotiate_caps). This timer is in addition to the T.30 specified T1 negotiation timer, and can be used to curtail a stuck negotiation where nevertheless V.21 messages are still being exchanged.

Following negotiation, and during page transmission, the page_timeout parameter to smfax_tx_page_process may be used to limit maximum page transmission time. Note this only limits the time transmitting high speed image data between retries, if page retries or T.30 ECM PPRs occur, the timeout will be reset for each new page or partial page transmission attempt.

Finally an idle_timeout (set for session through smfax_configure) allows earlier abandonment of fax transmission if it appears peer entity has ceased participating in fax session (for example if line goes silent but call has not been cleared).

E.2 Fax Reception

As for fax origination, the maximum elapsed time for the negotiation phase can be limited using the negotiation_timeout (set in smfax_negotiate_caps).

Following negotiation and during page reception, the page_timeout parameter in smfax_rx_page_process or smfax_rx_page_process_with_retry_timeout may be used to limit maximum page reception time. Note this only limits the time receiving high speed image data between retries, if page retries or T.30 ECM PPRs occur, the timeout will be reset for each new page or partial page reception attempt.

An additional retry timeout called total_page_timeout is provided in smfax_rx_page_process_with_retry_timeout which allows the total reception time including retries to be limited. This allows protection against a misbehaving originating fax that never abandons its retry sequence. If this timeout is used, it should be set to a large enough value to allow for an originator to legitimately fall back through modem speeds (a value in the order of 60 minutes might be reasonable in most environments).

As for fax origination an idle_timeout (again set for session through smfax_configure) allows earlier abandonment of fax transmission if it appears that the peer entity has ceased participating in the fax session (for example if the line goes silent but the call has not been cleared).
